

# Measurement of the branching fractions of $B_s^0 \rightarrow D_s^\mp K^\pm$ , $B_s^0 \rightarrow D_s^- \pi^+$ and $B^0 \rightarrow D_s^- K^+$

L.J. Bel

## Abstract

The relative branching fraction of the decay  $B_s^0 \rightarrow D_s^\mp K^\pm$  with respect to  $B_s^0 \rightarrow D_s^- \pi^+$  is determined from  $pp$  collision data corresponding to an integrated luminosity of  $3 \text{ fb}^{-1}$ . From the same data, the branching fractions of  $B_s^0 \rightarrow D_s^- \pi^+$  and  $B^0 \rightarrow D_s^- K^+$  are extracted with respect to  $B^0 \rightarrow D^- \pi^+$ . The obtained values for the  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B^0 \rightarrow D_s^- K^+$  branching fractions are more precise than the existing world average values.

# 1 Preface

The Standard Model (SM) of particle physics (see Fig. 1) has achieved tremendous success in explaining the interactions between the various (anti-)particles. Many phenomena that occur on the smallest scales we can currently probe can be explained, and quantum field theory elegantly integrates quantum mechanics with special relativity.

Figure 1: A visual representation of the Standard Model of particle physics. The size of the sphere corresponds to the particle's mass, and the colours and roman numerals indicate the generation of each particle. Each layer indicates the interaction (or force) that the particle above is sensitive to. For example, the quarks are the only fermions that are sensitive to all three forces.

Some long-standing problems, however, can not be solved by our current best understanding of the world of particles. Most notably, the difference between matter and anti-matter remains a mystery. Anti-matter is the exact opposite of matter in all regards (*i.e.*, all internal quantum numbers are inversed), and the two annihilate into photons (energy) when interacting (see Fig. 2). Because of this symmetry, one would expect matter and anti-matter to be created in equal amounts during the creation of the universe. This would mean that either all of it annihilated and nothing would exist, or that an amount of anti-matter equal to the amount of matter still exists somewhere in the universe. However, measurements indicate that more matter than anti-matter remains.

The inclusion of the Yukawa couplings in the SM – responsible for the interactions between matter and the Higgs boson – allows for a small violation in the matter–anti-matter symmetry. This symmetry is often called  $CP$  symmetry. This symmetry has been shown decades ago to be violated, but ever more precise measurements are still actively being pursued at the various particle detection experiments throughout the world. The best systems to study this  $CP$  symmetry involve particles that contain  $b$  quarks. The LHCb experiment at CERN is a dedicated experiment for the study of these  $b$  hadrons.

Figure 2: A particle and an anti-particle annihilate into two photons.

## 1.1 The LHC and the LHCb detector

The Large Hadron Collider (LHC) [1], located at CERN, Geneva, is the world's largest particle collider. Protons are injected as beams into a series of pre-accelerators, after which they enter the 27 km long LHC tunnel, up to 175 m deep beneath the surface. Inside this tunnel, the protons are accelerated to energies of up to 8 TeV and collided at one of the four interaction points in the LHC. At these points, huge particle detectors are located to detect the particles produced at the proton-proton collisions.

One of these experiments is the LHCb experiment [2] (see Fig. 3). This detector is very well suited for the study of  $b$  hadrons, particles that contain a  $b$  quark, in which  $CP$ -violating effects play an important role. LHCb is a forward-arm detector, justified by the fact that  $b$  hadrons are mainly produced in the forward region. It consists of a number of subdetectors, which together lead to a full reconstruction of the decay products of  $b$  hadrons [3].

Closest to the interaction point is the vertex locator (VELO) [4]. This silicon strip detector is located only 8 mm from the beam line, and together with the Tracker Turicensis (TT), Outer Tracker (OT) [5] and Inner Tracker (IT) [6], provides excellent particle tracking through the detector [7]. The LHCb magnet [8] bends the trajectories of charged particles, allowing for momentum measurements.

Particle identification (PID) is possible thanks to the two RICH subdetectors [9], together with the Electromagnetic and Hadronic Calorimeters (HCAL and ECAL) [10] and the muon system [11]. The RICH is capable of identifying any charged particle while the HCAL detects the energy deposit of both charged and neutral hadrons. The ECAL records the energy deposit of electrons and photons, and the muon system detects the muons, which leave tracks in the RICH but pass undetected through the calorimeters.

During the 2011 and 2012 data taking periods of the LHC, about 1400 bunches of approximately  $10^{13}$  protons were circulating in both directions. Due to the strong focussing of the beams at the interaction points, about  $10^{11}$   $b$  hadrons were produced in LHCb per year, which leads to about  $10^4$  detected  $b$  hadron decays per year, depending on the decay probability to the final state of interest.

Figure 3: A schematic representation of the LHCb detector.

## 1.2 The $B_s^0$ meson

The  $B_s^0$  meson<sup>1</sup> consists of an  $s$  (strange) quark and an anti- $b$  (bottom) quark. In this particle,  $CP$  violation plays a role in certain decays: the rate with which the particle decays into a particular final state may be different to that of the same process with anti-particles. One such decay is the decay into a  $D_s^\mp$  (containing  $\bar{c}s$  or vice versa) and a  $K^\pm$  meson (containing  $\bar{s}u$  or vice versa).

The decay  $B_s^0 \rightarrow D_s^\mp K^\pm$  is particularly sensitive to the so-called  $CP$ -violating observable  $\gamma$ . A measurement of  $\gamma$  using this decay will eventually be compared to other measurements of  $\gamma$ , that might hide the presence of new particles, potentially giving new insights into matter anti-matter differences. The first-order decay topologies of the decay  $B_s^0 \rightarrow D_s^- K^+$  are displayed as Feynman diagrams in Fig. 4.

The physics parameter measured in this analysis is the  $B_s^0 \rightarrow D_s^\mp K^\pm$  branching fraction, the probability for a  $B_s^0$  meson to decay to the  $D_s^\mp K^\pm$  final state. Because the number of produced  $B_{(s)}^0$  mesons is not known precisely, the branching fraction is normalised to another branching fraction. In this case, the process  $B_s^0 \rightarrow D_s^- \pi^+$  is used as normalisation.

<sup>1</sup>Throughout this document, inclusion of  $\bar{B}_s^0$  in the notation  $B_s^0$  is implied.

Figure 4: Feynman diagrams of the first-order contributions to the processes  $B_s^0 \rightarrow D_s^- K^+$  (left) and  $B_s^0 \rightarrow D_s^+ K^-$  (right).

Figure 5: Feynman diagrams of the first-order contributions to the processes  $B_s^0 \rightarrow D_s^- \pi^+$  (left) and  $B^0 \rightarrow D_s^- K^+$  (right).

66 However, to know the branching fraction of  $B_s^0 \rightarrow D_s^- \pi^+$ , it is in turn normalised to the  
 67 branching fraction of the decay  $B^0 \rightarrow D^- \pi^+$ . This value is obtained from the Particle  
 68 Data Group [12], the international collaboration that aims to provide a comprehensive  
 69 overview of all particle physics related parameters.

70 In the  $B_s^0 \rightarrow D_s^\mp K^\pm$  branching fraction analysis, another process appears: the decay  
 71  $B^0 \rightarrow D_s^- K^+$ . The lowest-order Feynman diagram of this process is show in Fig. 5.  
 72 The branching fraction of this decay is also measured, normalised to that of the decay  
 73  $B^0 \rightarrow D^- \pi^+$ . This means that in total three branching fractions are measured:

- 74 • The branching fraction  $\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)$ , normalised to  $\mathcal{B}(B^0 \rightarrow D^- \pi^+)$ ;
- 75 • The branching fraction  $\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)$ , normalised to  $\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)$ ;
- 76 • The branching fraction  $\mathcal{B}(B^0 \rightarrow D_s^- K^+)$ , normalised to  $\mathcal{B}(B^0 \rightarrow D^- \pi^+)$ .

77 The measurement of the branching fraction of the decay  $B_s^0 \rightarrow D_s^\mp K^\pm$  is a first step  
78 towards the precise determination of  $CP$  violation in this decay. In particular, an accurate  
79 determination is of interest, because:

- 80 • A previous measurement of  $\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)$  by LHCb [13], on only 10% of the cur-  
81 rently available data, yielded a value incompatible with theoretical expectations [14].  
82 By using the full data set, this analysis aims to confirm or refute this tension.
- 83 • To first order, only tree diagrams (such as the one in Fig. 4) play a role in the decay.  
84 Most theories for physics beyond the standard model (BSM) affect processes that  
85 involve loop diagrams. This branching fraction therefore gives a good gauge of the  
86 SM for other measurements to compare to.
- 87 • The difference between the branching fractions  $\mathcal{B}(B_s^0 \rightarrow D_s^- K^+)$  and  $\mathcal{B}(B_s^0 \rightarrow D_s^+ K^-)$   
88 *does* provide a measurement of  $CP$  violation. Until now, statistics have been a limiting  
89 factor for this measurement, but it might be feasible using the full LHCb dataset.

## 2 Introduction

The decay  $B_s^0 \rightarrow D_s^\mp K^\pm$  can occur through two different tree-level diagrams of similar magnitude. The branching fraction of this decay relative to that of  $B_s^0 \rightarrow D_s^- \pi^+$  has been previously measured by the LHCb collaboration [13] using data of  $pp$  collisions recorded in 2011, corresponding to an integrated luminosity of  $336 \text{ pb}^{-1}$ , at a centre-of-mass energy of 7 TeV. This measurement reported a value of  $0.0646 \pm 0.0043 \pm 0.0025$ . This value has been found to be incompatible with Standard Model (SM) expectations [14]. This note presents an update of this measurement, using  $pp$  collision data corresponding to  $3 \text{ fb}^{-1}$ , taken in 2011 ( $1 \text{ fb}^{-1}$ ) and 2012 ( $2 \text{ fb}^{-1}$ ) at  $\sqrt{s} = 7 \text{ TeV}$  and  $\sqrt{s} = 8 \text{ TeV}$ , respectively.

The branching fraction of  $B_s^0 \rightarrow D_s^\mp K^\pm$  is measured relative to that of the decay  $B_s^0 \rightarrow D_s^- \pi^+$  because of the symmetry between the two processes [15]. The diagrams are related to one another by changing the final state  $d$  quark with an  $s$  quark (or the pion with a kaon), and vice versa. The difference is that  $B_s^0 \rightarrow D_s^\mp K^\pm$  can decay into both charge conjugate final states, while the process  $B_s^0 \rightarrow D_s^- \pi^+$  can only do so through  $B_s^0 - \bar{B}_s^0$  mixing (see also Table 1). In addition, the decay  $B_s^0 \rightarrow D_s^\mp K^\pm$  can occur also through the exchange topology.

The branching fraction of  $B_s^0 \rightarrow D_s^- \pi^+$  is subsequently determined relative to that of the process  $B^0 \rightarrow D^- \pi^+$ , using the relative production rates of the  $B^0$  and  $B_s^0$  mesons  $f_s/f_d$ , determined with semileptonic  $B$  decays [16].

The branching fraction of the decay  $B^0 \rightarrow D_s^- K^+$  is also measured. It is normalised to that of  $B^0 \rightarrow D^- \pi^+$ . The process  $B^0 \rightarrow D_s^- K^+$  is interesting because the lowest-order decay topology is an exchange topology (see Fig. 6), featuring the exchange of a  $W$  boson between the two quarks of the original  $B_s^0$  meson. The measurement of  $\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)$  therefore provides a direct estimate of the magnitude of this type of diagrams.

Figure 6: Feynman diagram of the process  $B^0 \rightarrow D_s^- K^+$ .

## 114 3 Dataset and trigger

115 When the LHC is operational, about  $4 \times 10^7$  bunches of protons cross every second at so-  
116 called interaction points. Many of these events are of no particular interest to this analysis  
117 as they do not contain the relevant  $B_{(s)}^0$  decays. The event selection consists of a number  
118 of steps. First, the events pass through a trigger system, described in section 3.1. Next,  
119 the particles undergo offline reconstruction and a first, loose, selection (see section 3.2).  
120 Finally, the events pass another round of selection requirements specific to the analysis,  
121 which is described in the next chapter.

### 122 3.1 Dataset and Trigger

123 This analysis is performed on  $pp$  collision data corresponding to  $1 \text{ fb}^{-1}$  at  $\sqrt{s} = 7 \text{ TeV}$   
124 and  $2 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$ , for a total of  $3 \text{ fb}^{-1}$ . The data was taken using the triggers  
125 described in Refs. [17, 18].

126 The trigger consists of two stages: a hardware trigger, followed by a software trigger.  
127 The lowest trigger level is implemented in hardware, and selects events that contain a  
128 hadron with transverse energy greater than  $3.6 \text{ GeV}$ . The subsequent software trigger  
129 requires a two-, three- or four-track secondary vertex with a large sum of the transverse  
130 momentum,  $p_{\text{T}}$ , of the tracks and a significant displacement from the primary  $pp$  interaction  
131 vertices (PVs). At least one track should have  $p_{\text{T}} > 1.7 \text{ GeV}/c$  and  $\chi_{\text{IP}}^2$  with respect to any  
132 primary interaction greater than 16, where  $\chi_{\text{IP}}^2$  is defined as the difference in  $\chi^2$  of a given  
133 PV reconstructed with and without the considered candidate.

### 134 3.2 Stripping selection

135 The first event selection (“stripping”) is made based on kinematical and geometrical criteria.  
136 The stripping lines<sup>2</sup> proceed as follows. First, a  $D^{\pm}$  or  $D_s^{\pm}$  candidate is constructed by  
137 requiring a combination of three light hadrons (pions and kaons), each of which has a  
138 track  $\chi^2/\text{ndf}$  no greater than 3.0, a transverse momentum ( $p_{\text{T}}$ ) of at least  $100 \text{ MeV}/c$ , and  
139 a momentum  $p$  of at least  $1000 \text{ MeV}/c$ , typical for decay products of charmed mesons.

140 Furthermore, each final state particle originating from a  $B_{(s)}^0$  decay must be detached  
141 from the primary vertex. If the  $\chi^2/\text{ndf}$  of the primary vertex fit, denoted  $\chi_{\text{IP}}^2$ , increases  
142 by 4 or more when including the candidate track, the track is used.

143 In order to be combined, one of the  $D_{(s)}^{\pm}$  daughters must have a track with  $\chi^2/\text{ndf} <$   
144  $2.5$ ,  $p_{\text{T}} > 500 \text{ MeV}/c$ , and  $p > 5000 \text{ MeV}/c$ . The invariant mass of the combination  
145 must lie between  $1769.62$  and  $2068.49 \text{ MeV}/c^2$ , representing a mass window extending

---

<sup>2</sup>The stripping lines used are the same as were used in the previous measurement, the `B02DKD2HHH`  
and `B02DPiD2HHH Beauty2CharmLine` stripping lines in the `B2DX` family. The stripping has been updated  
from version 17, used in the previous analysis, to version 20 and 20r1 in this analysis for the 2012 and  
2011 data, respectively. The differences between versions 20 and 20r1 are limited to the ghost probability  
of the track of each individual particle being at most 0.4 and 0.3, respectively. The differences between  
these versions of stripping and version 17 are summarised in table 2.

Table 2: Differences between stripping versions 17, 20, and 20r1.

Variable	Stripping 17	Stripping 20	Stripping 20r1
Individual particles			
Track $\chi_{\text{IP}}^2$	> 4	> 3	> 3
Track ghost probability		< 0.4	< 0.3
Bachelor particle			
Track $\chi^2/\text{ndf}$	< 3	< 2.5	< 2.5
$D, D_s$			
Daughter track $\chi^2/\text{ndf}$	< 3	< 2.5	< 2.5
Global cuts			
#Long tracks	< 500	< 250	< 250

146 from  $100 \text{ MeV}/c^2$  below the  $D^\pm$  mass to  $100 \text{ MeV}/c^2$  above the  $D_s^\pm$  mass. The  $D_{(s)}^\pm$  candidate  
147 is also required to have a  $p_T$  of at least  $1800 \text{ MeV}/c$ , and it must have a distance of closest  
148 approach of at least  $0.5 \text{ mm}$ .

149 Finally, the  $D^\pm$  or  $D_s^\pm$  candidate must be combined with a bachelor pion or kaon. This  
150 bachelor particle is required to have a track  $\chi^2/\text{ndf}$  smaller than  $2.5$  and  $p_T > 500 \text{ MeV}/c$ ,  
151  $p > 5000 \text{ MeV}/c$ ,  $\chi_{\text{IP}}^2 > 4.0$ , and track ghost probability  $< 0.3$  ( $< 0.4$  for the 2012 data).  
152 The  $B_{(s)}^0$  candidate is a combination of the  $D_{(s)}^\pm$  candidate with this bachelor particle  
153 with an invariant mass between  $4750$  and  $6000 \text{ MeV}/c^2$  and a reconstructed lifetime of at  
154 least  $2 \text{ ps}$ . Some additional constraints are set on the final state particles before they are  
155 combined into a  $B_{(s)}^0$  candidate: at least one of the tracks should have  $p > 10 \text{ GeV}/c$  and  
156  $p_T > 1700 \text{ MeV}/c$ .

### 157 3.3 Simulated data

158 Simulated (Monte Carlo) data is used to estimate the invariant mass distributions of the  
159 background processes, as well as to obtain the shape of the invariant mass distributions of  
160 the signal decays, and to obtain the selection efficiency.

161 In the simulation,  $pp$  collisions are generated using PYTHIA [19] with a specific LHCb  
162 configuration [20]. Decays of hadronic particles are described by EVTGEN [21], in which  
163 final state radiation is generated using PHOTOS [22]. The interaction of the generated  
164 particles with the detector and its response are implemented using the GEANT4 toolkit [23]  
165 as described in Ref. [24].

## 4 Offline selection and efficiencies

While the stripping provides an efficient selection of candidate events, it does not sufficiently reject background events. In order to obtain a cleaner data sample, another sequence of cuts is applied to the stripped sample. The corresponding efficiencies must be understood and estimated in order to eventually correct the measured event yields. Except where noted, the same offline selection is applied to each decay type.

### 4.1 Offline selection

Two different kinds of cuts are applied to the data sample: kinematic cuts, which are cuts on the kinematic properties (such as invariant mass and momentum) of the candidates; and particle identification (PID) cuts, which use information from the RICH subdetectors of LHCb. Each cut is outlined below.

First, the events are limited to a reconstructed  $B_{(s)}^0$  meson mass between 5000 and 5800 MeV/ $c^2$ . Secondly, the reconstructed  $D^\pm$  ( $D_s^\pm$ ) candidate is required to fall in the mass window between 1844 and 1890 MeV/ $c^2$  (1944 and 1990 MeV/ $c^2$ ).

The next cuts are so-called fiducial cuts, which limit the data sample to the range detectable by the detector. This means limiting the  $p_T$  of the  $B_{(s)}^0$  candidate to the range [1500, 40000] MeV/ $c$ , and their pseudorapidity  $\eta$  to [2, 5].

The final states can be produced through different decay channels as well as the ones relevant to this analysis, such as the charmless decay  $B_s^0 \rightarrow KKK\pi$  under the process  $B_s^0 \rightarrow D_s^\mp K^\pm$ . To remove these background processes, the flight distance  $\chi^2$  of the  $D_{(s)}^\pm$  candidate is required to be greater than 2.0.

After these cuts, a PID cut is applied to the bachelor particle. These are cuts on the difference of the log-likelihood of the two particle hypotheses, called the  $DLL_{K\pi}$  and  $DLL_{p\pi}$  variables. The cuts are outlined, for each different decay channel, in Table 3.

Table 3: PID cuts on the final state light hadron candidates. The PID cuts on the bachelor particle and on the kaon with opposite charge relative to the  $D^-$  meson are both tight, as these cuts distinguish the different decays. Note that the  $DLL_{p\pi} - DLL_{K\pi}$  cuts in the  $B_s^0 \rightarrow D_s^- \pi^+$  and  $B_s^0 \rightarrow D_s^\mp K^\pm$  analyses are referring to the  $\Lambda_c^+$  veto procedure, as described in the text.

Cut	$B^0 \rightarrow D^- \pi^+$	$B_s^0 \rightarrow D_s^- \pi^+$	$B_s^0 \rightarrow D_s^\mp K^\pm$	Type
Bachelor	$DLL_{K\pi} < 0$	$DLL_{K\pi} < 0$	$DLL_{K\pi} > 5$	Tight
$\pi^\pm$ from $D_{(s)}^\pm$	$DLL_{K\pi} < 5$	$DLL_{K\pi} < 5$	$DLL_{K\pi} < 5$	Loose
	$DLL_{p\pi} < 15$			
$K^+$ from $D_{(s)}^-$	$DLL_{K\pi} > 0$	$DLL_{K\pi} > 0$	$DLL_{K\pi} > 0$	Loose
		$DLL_{p\pi} - DLL_{K\pi} < 0$	$DLL_{p\pi} - DLL_{K\pi} < 0$	
$K^-$ from $D_s^+$	–	$DLL_{K\pi} > 5$	$DLL_{K\pi} > 5$	Tight

190 Next, a multivariate algorithm [25, 26] is used to select candidates consistent with the  
 191 decay of a  $b$  hadron. This boosted decision tree (BDT) combines several kinematic and  
 192 geometric variables of the event and outputs a single number in the interval  $[-1, 1]$ . The  
 193 lower this number, the more likely the event is a background event; if the number is higher,  
 194 the event is more signal-like. The BDT has been trained (calibrated) by supplying data  
 195 in the relevant mass window, weighted with its similarity to actual signal events; and a  
 196 sample of background events in the upper mass sideband with an invariant  $D_{(s)}^-\pi^+$  mass  
 197  $> 5500$  MeV. This BDT is the same as the one used in the time-dependent  $B_s^0 \rightarrow D_s^\mp K^\pm$   
 198 analysis [27]. The value resulting from this BDT is required to be greater than 0.3. This  
 199 value rejects most of the background, without significantly suppressing the signal.

200 Finally, in the analyses containing a  $D_s^\pm$  meson, a veto is applied to reduce the  
 201 contribution of the  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  ( $\Lambda_c^+ \rightarrow pK^- \pi^+$ ) background process, resulting from the  
 202 proton-to-kaon misidentification by the RICH detector. This is done by reconstructing  
 203 the final state  $K^+$  meson from the  $D_s^-$  candidate under the  $p$  hypothesis and calculating  
 204 the invariant  $D_s^-$  mass. If  $\text{DLL}_{p\pi} - \text{DLL}_{K\pi}$  for a particular event is smaller than 0 and  
 205 this mass is within  $21 \text{ MeV}/c^2$  of the  $\Lambda_c^+$  mass  $2286.46 \text{ MeV}/c^2$ , the event is removed from  
 206 the sample. This process, referred to from now on as the  $\Lambda_c^+$  veto procedure, ensures an  
 207 almost fully efficient reduction of the background process  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$ .

## 208 4.2 Selection efficiencies

209 In order to correctly determine the ratio of branching fractions, the relative reconstruction  
 210 and selection efficiencies of the channels must be taken into account. Each of the cuts  
 211 outlined in the previous section has a specific efficiency for each process. All signal decays  
 212 studied here have a very similar decay topology, but nevertheless these efficiencies may be  
 213 different for each of the processes.

214 The efficiencies of the kinematic selection criteria are determined from simulation (see  
 215 section 3.3), as the kinematic distributions are well modelled. These efficiencies are listed  
 216 in Tables 4, 5, and 6. It should be noted that certain trigger requirements are applied  
 217 within the stripping selection. The trigger cuts listed in the tables require in addition that  
 218 the trigger decision was applied to the signal tracks.

219 In contrast, the PID performance to select kaons and pions is modelled less accurately,  
 220 and needs to be determined from data. These efficiencies depend strongly on the kinematics  
 221 of the particles, as well as properties of the events in which they occur. The kaon-pion  
 222 efficiency is taken from a dedicated sample of  $D^{*+} \rightarrow (D^0 \rightarrow K^- \pi^+) \pi^+$  decays, which  
 223 provide a clean resonance peak at  $2010 \text{ MeV}$  in which the two resulting pions have the same  
 224 charge. Because of the small mass difference between the  $D^{*\pm}$  meson and the  $(\bar{D})^0$  meson,  
 225 the bachelor pion is slow and easily identifiable. Using the fact that the pion charges  
 226 are identical, unambiguous identification of the final state particles is possible without  
 227 requiring PID information from the RICH, yielding an accurate estimate of the pion-kaon  
 228 PID efficiency. The proton-pion efficiency is determined in a similar way from  $\Lambda \rightarrow p\pi^-$   
 229 decays.

230 The variables in which the PID performance is determined are track momentum, track

231 pseudorapidity  $\eta$ , and number of tracks in the event. PID performance histograms are  
 232 generated by calculating, in bins of these three variables, the fraction of correctly identified  
 233 particles, yielding a three-dimensional histogram with values between 0 and 1. This is a  
 234 statistical method and does not yield exact values for specific decay channels, but it does  
 235 provide a good data-driven estimate for the PID performance.

236 By weighting a Monte Carlo sample of simulated  $B^0 \rightarrow D^- \pi^+$ ,  $B_s^0 \rightarrow D_s^- \pi^+$  or  
 237  $B_s^0 \rightarrow D_s^\mp K^\pm$  data to the PID performance histograms created this way, an estimate of the  
 238 PID efficiency of those respective processes is obtained. The results of these performance  
 239 estimations are summarised in Table 7. This reweighting is performed in the three variables  
 240 mentioned above.

Table 4: Efficiencies of the kinematic cuts of  $B^0 \rightarrow D^- \pi^+$ .

	$\varepsilon_{\text{rel}}$ (%)	$\varepsilon_{\text{cum}}$ (%)
Generator level efficiency	$16.10 \pm 0.09$	$16.10 \pm 0.09$
Reconstruction and stripping	$13.65 \pm 0.03$	$2.20 \pm 0.01$
Trigger cuts	$96.70 \pm 0.10$	$2.12 \pm 0.01$
$B_{(s)}^0$ mass window cuts	$99.32 \pm 0.04$	$2.11 \pm 0.01$
$D_{(s)}^\pm$ mass window cuts	$95.65 \pm 0.11$	$2.02 \pm 0.01$
Fiducial cuts	$99.53 \pm 0.04$	$2.01 \pm 0.01$
Flight distance cuts	$94.24 \pm 0.12$	$1.89 \pm 0.01$
BDT cuts	$95.62 \pm 0.11$	$1.82 \pm 0.01$
Total		$1.82 \pm 0.01$

Table 5: Efficiencies of the kinematic cuts of  $B_s^0 \rightarrow D_s^- \pi^+$ .

	$\varepsilon_{\text{rel}}$ (%)	$\varepsilon_{\text{cum}}$ (%)
Generator level efficiency	$17.06 \pm 0.38$	$17.06 \pm 0.38$
Reconstruction and stripping	$14.37 \pm 0.03$	$2.45 \pm 0.05$
Trigger cuts	$93.53 \pm 0.13$	$2.29 \pm 0.05$
$B_{(s)}^0$ mass window cuts	$99.47 \pm 0.04$	$2.28 \pm 0.05$
$D_{(s)}^\pm$ mass window cuts	$97.27 \pm 0.09$	$2.22 \pm 0.05$
Fiducial cuts	$99.41 \pm 0.04$	$2.21 \pm 0.05$
Flight distance cuts	$87.78 \pm 0.17$	$1.94 \pm 0.04$
BDT cuts	$96.22 \pm 0.10$	$1.88 \pm 0.04$
$\Lambda_c^+$ veto	$99.08 \pm 0.05$	$1.86 \pm 0.04$
Total		$1.86 \pm 0.04$

Table 6: Efficiencies of the kinematic cuts of  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B^0 \rightarrow D_s^- K^+$ .

$B_s^0 \rightarrow D_s^\mp K^\pm$	$\varepsilon_{\text{rel}}$ (%)	$\varepsilon_{\text{cum}}$ (%)
Generator level efficiency	$17.72 \pm 0.07$	$17.72 \pm 0.07$
Reconstruction and stripping	$15.08 \pm 0.05$	$2.67 \pm 0.01$
Trigger cuts	$93.64 \pm 0.17$	$2.50 \pm 0.01$
$B_{(s)}^0$ mass window cuts	$99.72 \pm 0.04$	$2.49 \pm 0.01$
$D_{(s)}^\pm$ mass window cuts	$97.54 \pm 0.11$	$2.43 \pm 0.01$
Fiducial cuts	$99.44 \pm 0.05$	$2.42 \pm 0.01$
Flight distance cuts	$87.91 \pm 0.23$	$2.13 \pm 0.01$
BDT cuts	$96.47 \pm 0.13$	$2.06 \pm 0.01$
$\Lambda_c^+$ veto	$99.13 \pm 0.06$	$2.05 \pm 0.01$
Total		$2.05 \pm 0.01$
$B^0 \rightarrow D_s^- K^+$	$\varepsilon_{\text{rel}}$ (%)	$\varepsilon_{\text{cum}}$ (%)
Generator level efficiency	$15.27 \pm 0.04$	$15.27 \pm 0.04$
Reconstruction and stripping	$15.08 \pm 0.05$	$2.30 \pm 0.01$
Trigger cuts	$92.14 \pm 0.80$	$2.12 \pm 0.02$
$B_{(s)}^0$ mass window cuts	$99.47 \pm 0.22$	$2.11 \pm 0.02$
$D_{(s)}^\pm$ mass window cuts	$97.26 \pm 0.49$	$2.05 \pm 0.02$
Fiducial cuts	$99.20 \pm 0.26$	$2.03 \pm 0.02$
Flight distance cuts	$88.43 \pm 0.95$	$1.80 \pm 0.03$
BDT cuts	$96.02 \pm 0.58$	$1.74 \pm 0.03$
$\Lambda_c^+$ veto	$99.03 \pm 0.29$	$1.72 \pm 0.03$
Total		$1.72 \pm 0.03$

Table 7: Efficiencies of the PID cuts. Note that the PID efficiency for the selection of the bachelor particle is not independent of that of the  $D_{(s)}^\pm$  daughters.

	PID efficiency (%)			
	$B^0 \rightarrow D^- \pi^+$	$B_s^0 \rightarrow D_s^- \pi^+$	$B^0 \rightarrow D_s^- K^+$	$B_s^0 \rightarrow D_s^\mp K^\pm$
Cut on bachelor	$84.27 \pm 0.06$	$84.24 \pm 0.06$	$70.55 \pm 0.85$	$69.70 \pm 0.20$
Cut on $D_{(s)}^\pm$ meson	$87.91 \pm 0.05$	$79.72 \pm 0.10$	$80.42 \pm 0.56$	$79.59 \pm 0.14$
Total	$74.29 \pm 0.07$	$67.76 \pm 0.10$	$58.11 \pm 0.82$	$56.64 \pm 0.19$

Table 8: ( $\pi \leftrightarrow K$ )-misidentification rates of the PID cuts. Note that again the bachelor and  $D_{(s)}^\pm$  meson misidentification rates are not independent of one another.

	Misidentification rate (%)			
	$B^0 \rightarrow D^- \pi^+$	$B_s^0 \rightarrow D_s^- \pi^+$	$B^0 \rightarrow D_s^- K^+$	$B_s^0 \rightarrow D_s^\mp K^\pm$
Cut on bachelor	$9.92 \pm 0.05$	$10.14 \pm 0.05$	$2.13 \pm 0.05$	$2.12 \pm 0.01$
Cut on $D_{(s)}^\pm$ meson	$15.42 \pm 0.10$	$2.63 \pm 0.02$	$2.79 \pm 0.13$	$2.63 \pm 0.02$
Total	$1.625 \pm 0.018$	$0.261 \pm 0.004$	$0.061 \pm 0.003$	$0.057 \pm 0.001$

## 5 Fitting

### 5.1 Background components

Various background components play a role in the processes  $B^0 \rightarrow D^- \pi^+$ ,  $B_s^0 \rightarrow D_s^- \pi^+$ , and  $B_s^0 \rightarrow D_s^\mp K^\pm$ . There are background contributions resulting from misidentification, such as  $B_s^0 \rightarrow D_s^- \pi^+$  under  $B_s^0 \rightarrow D_s^\mp K^\pm$ , where one of the final state particles is wrongly identified. The excellent particle identification in LHCb reduces each of those by about 85 – 98% (see Table 8), so only a small contribution remains. There are partially reconstructed background processes, such as  $B_s^0 \rightarrow D_s^- (K^{*+} \rightarrow K^+ \pi^0)$ , where a neutral particle is not reconstructed. The invariant mass of these processes is shifted to lower values, and, because the momentum of the missed particle is unknown, smeared out. Finally, there is a contribution from combinatorial background – random tracks that accidentally form a  $D_s^\mp K^\pm$  candidate in the relevant mass range.

The relevant background components are enumerated in Table 9. Each of these components is taken into account when fitting the invariant mass distribution, in order to obtain an accurate value for the signal yield. The shape of each of them, known as a “template”, is taken from simulations, generated by PYTHIA versions 6 and 8 (see section 3.3). These events are simulated at a centre-of-mass energy of  $\sqrt{s} = 8$  TeV. To improve the accuracy of the fit, the yield of each of the background components is estimated using prior knowledge. This information includes the relative branching fractions,  $B^0$  and  $B_s^0$  meson production fractions ( $f_d$  and  $f_s$ , respectively), and reconstruction and selection efficiency. The reconstruction efficiency in turn depends on the (PID) performance and the efficiency of the stripping and track reconstruction applied to the raw data, as well as the efficiency of the cuts on the mass range of the  $B_{(s)}^0$ , the mass range of the  $D_{(s)}^\pm$ , and the BDT efficiency (see section 4).

The mass distribution for some background components are not distinct enough to allow for a precise yield estimate from the fit. Therefore, the yield is constrained in the fit, but not fixed. These components are marked in the “GC” (Gaussian constraint) column of Table 9. The corresponding Gaussian has its mean set to the calculated yield estimation, and its width to 10% of that number. This value is an approximation of the total error on the estimated yields, to correct for statistical and systematic deviations from that number.

The templates are obtained from fits to the simulated data, resulting in a non-parametric function. This fit takes for each data point a Gaussian distribution, then smears them out over the mass range to obtain a smooth shape [28]. In this process, the simulated data for magnet up and magnet down have been combined to increase the statistical precision. The resulting templates are shown in appendix A.

The PID performance is determined in bins of three different variables – hadron momentum, hadron pseudorapidity, and total number of tracks in the event – to give an estimate of the number of (in)correct identifications performed on a specific kind of particle in a sample. This is done separately for both magnet polarities. The relevant momentum and angular distributions of the final state kaons and pions are taken from simulation, which is assumed to have similar distributions in the three PID variables. The background

282 templates are then reweighted to the PID performance in bins of the three variables. The  
283 PID reweighting also contributes the only difference between the two magnet polarities in  
284 the background templates.

Table 9: Background and signal yield estimates of the different processes at hand:  $B^0 \rightarrow D^- \pi^+$ ,  $B_s^0 \rightarrow D_s^- \pi^+$ , and  $B_s^0 \rightarrow D_s^\mp K^\pm$ . Type PR means partially reconstructed, M means misidentified, and S means signal. GC implies that the yield is Gaussian constrained. Prod. is the hadronisation fraction relative to that of the  $B^0$  meson,  $f_d$ . PID is the probability of correctly identifying the final state particles of the given process. Rel. reco is the relative reconstruction efficiency, normalised to that of the parent process. This is a combination of mass range cuts, stripping efficiency, BDT cut, and  $\Lambda_c^+$  veto, as appropriate per analysis. Rel. yield is the relative yield, again normalised to that of the parent process, and Exp. yield is the expected yield. The expected yield from  $B^0 \rightarrow D^- \pi^+$  was taken from the fit, and the other yields are estimated relative to the  $B^0 \rightarrow D^- \pi^+$  yield.

Process	Background	Type	GC	$\mathcal{B}/10^{-4}$	Prod.	PID	Rel. reco	Rel. yield	Exp. yield / $10^3$

285 **5.2 Signal shapes**

286 The total signal yield is obtained by fitting the signal peak with a signal shape, of which  
 287 different models have been tested. The tails on each side of the signal peak arise from  
 288 detector resolution effects and from energy loss due to final state radiation. The various  
 289 tested models share a Gaussian-like middle part, surrounded by two (possibly asymmetric)  
 290 decreasing tails. The shape that was eventually chosen in the fits is the double Crystal  
 291 Ball function [29]. This function consists of a central Gaussian part with on each side an  
 292 exponential tail. The full definition of the double Crystal Ball function is given in Eq. (1).

$$\begin{aligned}
 & f(x; \bar{x}, \sigma, \alpha_1, \alpha_2, n_1, n_2, \varepsilon) = \\
 & N \begin{cases} \varepsilon \left( \frac{n_1}{|\alpha_1|} \right)^{n_1} \exp\left(-\frac{|\alpha_1|}{2}\right) \left( \frac{n_1}{|\alpha_1|} - |\alpha_1| - \frac{x - \bar{x}}{\sigma} \right)^{-n_1} & \text{for } \frac{x - \bar{x}}{\sigma} > \alpha_1 \\
 (1 - \varepsilon) \left( \frac{n_2}{|\alpha_2|} \right)^{n_2} \exp\left(-\frac{|\alpha_2|}{2}\right) \left( \frac{n_2}{|\alpha_2|} - |\alpha_2| - \frac{x - \bar{x}}{\sigma} \right)^{-n_2} & \text{for } \frac{x - \bar{x}}{\sigma} < \alpha_2 \\
 \exp\left(-\frac{(x - \bar{x})^2}{2\sigma^2}\right) & \text{otherwise.} \end{cases} \quad (1)
 \end{aligned}$$

293 This function has seven parameters: the mean  $\bar{x}$  and standard deviation  $\sigma$  of the  
 294 Gaussians (shared between them), the exponential constants  $\alpha_{1,2}$  of the two tails, and  
 295 the distances  $n_{1,2}$  from the mean at which the tails start (measured in units of  $\sigma$ ). The  
 296 parameter  $\varepsilon \in [0, 1]$  represents the relative fraction of the two Crystal Ball functions. This  
 297 parameter has been fixed to 0.5 in all applications of this function throughout the full  
 298 analysis, as the central Gaussian is chosen to be the same for both Crystal Ball functions.  
 299  $N$  is not a parameter of the function, rather it is an overall normalization factor depending  
 300 on the parameters.

301 Results of this fit to simulated data samples are shown in Fig. 7, and the parameter  
 302 values in Table 10. Other functions that have been investigated for use in the mass fit, as  
 303 well as results from fits to simulated signal samples, can be found in appendix B.

Table 10: Results of double Crystal Ball function fits to simulated signal samples.

Parameter	Fitted value
$B^0 \rightarrow D^- \pi^+$	
Fract <sub>Sig-CBs</sub>	0.500000

$n_2$	$6.27 \pm 1.22$
$\sigma$	$15.8 \pm 0.2$

Figure 7: Double Crystal Ball function signal fits for (a)  $B^0 \rightarrow D^- \pi^+$ , (b)  $B_s^0 \rightarrow D_s^- \pi^+$ , and (c)  $B_s^0 \rightarrow D_s^- K^+$ .

### 5.3 Combinatorial

Combinatorial background events arise from the  $D_{(s)}^\pm$  candidates, combined with a random track to form a fake  $B_{(s)}^0$  candidate, or from fake  $D_{(s)}^\pm$  candidates. Most of the contribution of the combinatorial background is rejected by the BDT selection (see section 4), but some still remains and must be accounted for in the fit.

The shape of the combinatorial background is estimated from wrong-sign samples. These are  $D_{(s)}^\pm \pi^\pm$  and  $D_s^\pm K^\pm$  candidates that can not have originated from  $B_{(s)}^0$  decays. Like true combinatorial background, these events do not actually represent  $B_{(s)}^0$  candidates; rather, they are combinations of random tracks. These samples are data samples acquired, reconstructed and stripped in the same way as the normal data samples. They are subsequently fitted with a function of the form

$$f(x; p_0, p_1) = p_0 + (1 - p_0) \exp(p_1 x).$$

The results of these fits are displayed in Table 11. The shape of the wrong-sign mass distributions for  $D_s^+$  candidates is consistent with a pure exponential, *i.e.* with a vanishing value for  $p_0$ . The plots can be found in App. C.

Table 11: Results from fits to the wrong-sign samples for each of the decays. The fits are performed in the  $[5000, 5800]$  MeV/ $c^2$  mass range for  $B^0 \rightarrow D^- \pi^+$  and in the  $[5100, 5800]$  MeV/ $c^2$  mass range for  $B_s^0 \rightarrow D_s^- \pi^+$  and  $B_s^0 \rightarrow D_s^\mp K^\pm$ , and are done separately for magnet up and down.

Wrong-sign sample	$p_0$	$p_1$
$B^0 \rightarrow D^\mp \pi^\mp$ (magnet up)	$0.4512 \pm 0.0448$	$-0.0031 \pm 0.0003$
$B^0 \rightarrow D^\mp \pi^\mp$ (magnet down)	$0.1164 \pm 0.1306$	$-0.0019 \pm 0.0003$
$B_s^0 \rightarrow D_s^\mp \pi^\mp$ (magnet up)	$0.0000 \pm 0.0013$	$-0.00319 \pm 0.00005$
$B_s^0 \rightarrow D_s^\mp \pi^\mp$ (magnet down)	$0.0000 \pm 0.0042$	$-0.00298 \pm 0.00005$
$B_s^0 \rightarrow D_s^\mp K^\mp$ (magnet up)	$0.0111 \pm 0.7533$	$-0.0020 \pm 0.0004$
$B_s^0 \rightarrow D_s^\mp K^\mp$ (magnet down)	$0.0125 \pm 0.7577$	$-0.0019 \pm 0.0004$

## 318 5.4 The fit to $B^0 \rightarrow D^- \pi^+$

319 The fit to  $B^0 \rightarrow D^- \pi^+$  candidates is performed on the interval [5000, 5800] MeV/ $c^2$ . The  
320 background templates are obtained from simulated data with 2012 conditions at a centre-  
321 of-mass energy of 8 TeV (with the exception of the  $B^0 \rightarrow D^{*-} \pi^+$  background, which was  
322 simulated with 2011 conditions, at a centre-of-mass energy of 7 TeV). All these shapes  
323 are shown in appendix A.1. The yields of the background components resulting from a  
324 misidentified final-state particle, such as the decays  $B^0 \rightarrow D^- K^+$  or  $B_s^0 \rightarrow D_s^- \pi^+$ , are  
325 Gaussian constrained. Because the estimates of all background components (see Table 9)  
326 use the output of this fit (the  $B^0 \rightarrow D^- \pi^+$  yield) as the input to calculate all the relative  
327 yields, an iterative approach has been applied, where the output of the fit was fed as input  
328 to the background estimates until the numbers stabilised.

329 The parameters of the double Crystal Ball function used to model the core of the  
330 signal shape, the mean  $\bar{x}$  and standard deviation  $\sigma$ , were allowed to vary in the fit within  
331 the intervals [5000, 5800] MeV/ $c^2$  and [0, 20] MeV/ $c^2$ , respectively. The parameters that  
332 describe the tails,  $n_{1,2}$  and  $\alpha_{1,2}$ , were left free in the fit.

333 The fit is shown in Fig. 8, and the corresponding values are displayed in Table 12. The  
334 total  $B^0 \rightarrow D^- \pi^+$  yield is about 460 000 events.

## 335 5.5 The fit to $B_s^0 \rightarrow D_s^- \pi^+$

336 The  $B_s^0 \rightarrow D_s^- \pi^+$  fit is performed on the mass range [5100, 5800] MeV/ $c^2$ . The background  
337 templates are taken from 2012 simulations at a centre-of-mass energy of 8 TeV. These  
338 shapes can be found in appendix A.2. The tail parameters of the  $B_s^0 \rightarrow D_s^- \pi^+$  signal  
339 shape are fixed to the values obtained in the signal shape fit to simulated events (see  
340 section 5.2). The mean of the  $B_s^0 \rightarrow D_s^- \pi^+$  signal process is fixed to the  $B^0$  mass, and  
341 its width and tail parameters are fixed to those of the  $B_s^0 \rightarrow D_s^- \pi^+$  signal shape. As in  
342 the  $B^0 \rightarrow D^- \pi^+$  fit, the yields of the misidentified background components, in this case  
343 only the decay  $B^0 \rightarrow D^- \pi^+$ , are Gaussian constrained around the values given in Table 9.  
344 The fit results are displayed in Table 13 and Fig. 9. The total  $B_s^0 \rightarrow D_s^- \pi^+$  yield is about  
345 76 000 events.

## 346 5.6 The fit to $B_s^0 \rightarrow D_s^\mp K^\pm$

347 The fit to  $B_s^0 \rightarrow D_s^\mp K^\pm$ , like the  $B_s^0 \rightarrow D_s^- \pi^+$  fit, is performed on the mass range  
348 [5100, 5800] MeV/ $c^2$ , and its background templates are also taken from simulated data at  
349 a centre-of-mass energy of 8 TeV with 2012 conditions. These shapes can be found in  
350 appendix A.3. The yield of each of these background components is Gaussian constrained  
351 in the fit. The predicted  $B_s^0 \rightarrow D_s^\mp K^\pm$  yield to which these constraints are normalised  
352 is calculated by multiplying the expected  $B_s^0 \rightarrow D_s^- \pi^+$  yield with the estimated relative  
353 efficiencies.

354 The fit results are displayed in Table 14 and Fig. 10. The total  $B_s^0 \rightarrow D_s^\mp K^\pm$  yield is  
355 about 5000 events, and the  $B^0 \rightarrow D_s^- K^+$  yield about 2400.

## 356 6 Systematic uncertainties and consistency checks

357 The systematic uncertainties in this analysis arise from uncertainties on the efficiency  
358 due to the kinematic and PID cuts (see section 4) and from assumptions in the fit model  
359 (described in section 5). Section 6.5 describes checks performed to assert the internal  
360 consistency of the analysis.

### 361 6.1 Uncertainty on selection efficiency

362 The efficiency of the kinematic selection carries a systematic uncertainty. This uncertainty  
363 is dominated by the uncertainty on the BDT selection efficiency, which relies on the  
364 agreement between data and simulation. This agreement has been studied in detail in the  
365 analysis of  $B^0 \rightarrow D^- \pi^+$  and  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  [30, 31], and the same method has been used in  
366 this analysis. The method gauges the systematic uncertainty on the selection efficiency by  
367 applying the BDT cut to two samples of simulated data: one which is reweighted to more  
368 closely resemble actual data, and one which is not. The difference in efficiency then gives  
369 a measure of the systematic uncertainty on the BDT selection. The uncertainty on the  
370 BDT efficiency is 2.8%.

### 371 6.2 Uncertainties from PID selection

372 The uncertainties on the PID efficiency have been calculated for bachelor kaons and pions  
373 as well as  $D_{(s)}^\pm$  daughters in Ref. [32]. These values have been obtained by using a simulated  
374 reference sample to determine the PID efficiency, rather than  $D^*$  data. The difference  
375 in PID efficiency then gives a measure of the systematic on the PID. In the systematic  
376 uncertainties of each signal decay (see Table 15) the PID uncertainties of both particles  
377 are listed. In the systematic uncertainties on the ratios (see Table 17), only the PID  
378 uncertainties have been taken into account for the particles that are different between  
379 the two decays (*e.g.* only the bachelor particle in the ratio of the decays  $B_s^0 \rightarrow D_s^- \pi^+$  and  
380  $B_s^0 \rightarrow D_s^\mp K^\pm$ ).

### 381 6.3 Uncertainties from the fit model

382 To test the robustness of the fit model, and to obtain a numerical systematic uncertainty,  
383 several variations of the fit model are applied. Each time, the change in signal yield is  
384 observed, and taken as a systematic uncertainty. Table 15 lists all these uncertainties.  
385 Below, each of them is motivated and described in more detail.

#### 386 Different combinatorial shape

387 A variation of the combinatorial shape is tested: rather than fitting to a constant  
388 plus an exponential, the combinatorial is modelled using only an exponential.

#### 389 Vary background estimates by $\pm 10\%$

390 The means of the Gaussian constraints are increased or decreased by 10%. The  
391 respective widths are recalculated as 10% of the new value.

392 **Different background templates**

393 The background templates are made using data simulated with 2011 conditions  
394 at  $\sqrt{s} = 7$  TeV, rather than 2012 ( $\sqrt{s} = 8$  TeV). A small shift in the mass values  
395 and small differences in the shape can be caused by the different centre-of-mass  
396 energy (see Fig. 12). In the  $B^0 \rightarrow D^- \pi^+$  fit, the tail parameters are fixed to the  
397 values obtained in the original fit, to prevent this variation from being taken over by  
398 changes in the tail parameters.

399 **Reduced fit range** ( $B^0 \rightarrow D^- \pi^+$  only)

400 The effect of uncertainties in the lower mass sideband of the fit model on the signal  
401 yield is estimated by a separate fit in the mass range  $[5100, 5800]$  MeV/ $c^2$ , ignoring  
402 the events in the range  $[5000, 5100]$  MeV/ $c^2$ . The results of this fit are displayed in  
403 Fig. 13.

404 **Fix tail parameters** ( $B^0 \rightarrow D^- \pi^+$  only)

405 In contrast to the fits to the processes  $B_s^0 \rightarrow D_s^- \pi^+$  and  $B_s^0 \rightarrow D_s^\mp K^\pm$ , the tail  
406 parameters of the decay  $B^0 \rightarrow D^- \pi^+$  are left free in the fit, as fixing them reduces  
407 the quality of the fit. In this variation, they are fixed to the values resulting from the  
408 signal shape fit to simulated data (see section 5.2). For convenience, the parameter  
409 values are reproduced in Table 16. The double Crystal Ball shapes resulting from  
410 those tail parameter values are shown in Fig. 11. The other two parameters are left  
411 free in the fit, and to provide a proper comparison, they have been set to the values  
412 from the data fit in the figure.

413 Because in the fits to the other decay modes the tail parameters are fixed to the  
414 values obtained from simulation, this variation can not be applied. However, if  
415 the assumption is made that the data-simulation differences are similar across the  
416 different simulated decays, the value obtained for the  $B^0 \rightarrow D^- \pi^+$  analysis can be  
417 used in the others as well.

418 **Omit**  $A_b^0 \rightarrow D_s^{-(*)} p$  ( $B_s^0 \rightarrow D_s^\mp K^\pm$  only)

419 The decay  $A_b^0 \rightarrow D_s^{-(*)} p$  has not been measured yet, and the branching fraction  
420 used to estimate its yield in this analysis is the current best upper limit. If the  
421 actual branching fraction is lower by any significant amount, the decay would not be  
422 measurable anymore. This is checked here by omitting it from the fit.

Table 15: Systematic uncertainties on each of the fits. The fit model variations are described in more detail in the text. The totals are calculated by adding the relevant values in quadrature.

	Relative change in signal yield (%)			
	$B^0 \rightarrow D^- \pi^+$	$B_s^0 \rightarrow D_s^- \pi^+$	$B^0 \rightarrow D_s^- K^+$	$B_s^0 \rightarrow D_s^- K^\pm$

$n_2$	$3.04 \pm 0.26$	$118.25 \pm 14.53$

Figure 11: Comparison of double Crystal Ball functions with tail parameters obtained from simulated  $B^0 \rightarrow D^- \pi^+$  events (blue curve) and data (red dashed curve), in arbitrary units. The mean and  $\sigma$  are set to the values obtained in the data fit.

Figure 12: Comparisons of partially reconstructed and misidentified data simulated under 2011 (red dashed curve) and 2012 (blue curve) conditions, in arbitrary units, for (a)  $B_s^0 \rightarrow D_s^- \pi^+$  under  $B^0 \rightarrow D^- \pi^+$ , (b)  $B^0 \rightarrow D^- \pi^+$  under  $B_s^0 \rightarrow D_s^- \pi^+$ , (c)  $B_s^0 \rightarrow D_s^{*-} \pi^+$  under  $B_s^0 \rightarrow D_s^{\mp} K^{\pm}$ , and (d)  $B_s^0 \rightarrow D_s^{*-} \rho^+$  under  $B_s^0 \rightarrow D_s^{\mp} K^{\pm}$ . Note that each shape used in the fit is normalised with a parameter corresponding to the yield of that particular background component.

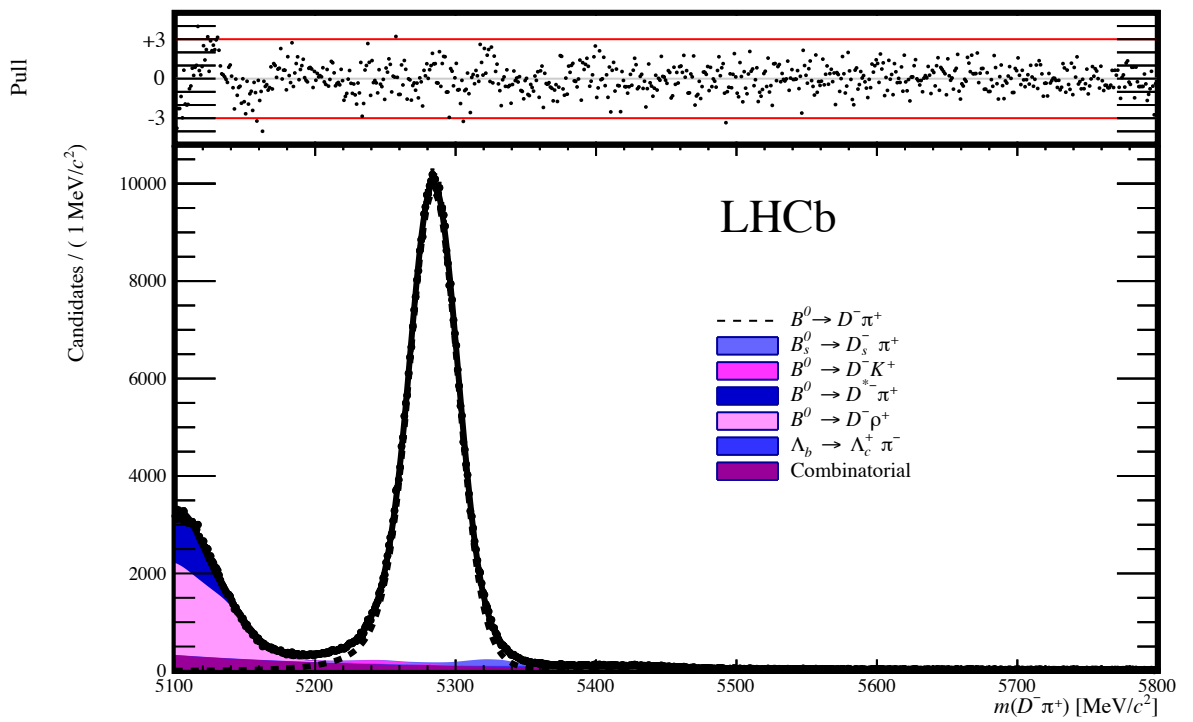

Figure 13: Mass fit to the process  $B_s^0 \rightarrow D_s^- \pi^+$ , in the reduced mass range  $[5100, 5800] \text{ MeV}/c^2$ .

## 6.4 Total systematic uncertainties per ratio

When calculating ratios of branching fractions, some systematic uncertainties appear in both the numerator and the denominator. To avoid double counting these errors, only a selection of uncertainties is used for the final systematic error on each ratio of branching fractions. The resulting systematic uncertainties are listed in Table 17.

### $B_s^0 \rightarrow D_s^- \pi^+$ relative to $B^0 \rightarrow D^- \pi^+$

Of the systematic uncertainties on the PID, only those related to differently identified particles in the final state need to be taken into account. In this case, that amounts to the  $D_{(s)}^\pm$  meson final state pions and kaons. The resulting uncertainty is 1.1%.

Of the fit variations, the different combinatorial shape is fully taken into account, as the combinatorial shapes may be different for the two processes. For the constraint mean shifts and different background templates, only the largest error between the two analyses is used, as these represent fluctuations in the simulated data which are assumed to be similar. The constrained fit range and fixed signal tail parameters are unique to the  $B^0 \rightarrow D^- \pi^+$  analysis, and as such are also taken fully into account. In particular, any uncertainty on the signal shape tail parameters of the  $B_s^0 \rightarrow D_s^- \pi^+$  peak is assumed to be covered this way. Adding all these numbers in quadrature, an uncertainty of 2.8% is obtained.

The uncertainty on the offline selection of 2.8% is applied once, as the two selection procedures are very similar, and the BDT cut is identical.

### $B_s^0 \rightarrow D_s^\mp K^\pm$ relative to $B_s^0 \rightarrow D_s^- \pi^+$

To determine the systematic uncertainty on the ratio of  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B_s^0 \rightarrow D_s^- \pi^+$ , similar arguments are used as above. This leads to a systematic uncertainty from PID of 1.0%.

The different combinatorial shape uncertainties are again taken fully into account. The omission of  $\Lambda_b^0 \rightarrow D_s^{-(*)} p$  is only present in the  $B_s^0 \rightarrow D_s^\mp K^\pm$  analysis, and is used. The other uncertainties are all expected to be similar in the two analyses, and again for each only the largest value is used. The total uncertainty obtained this way is 1.2%.

The uncertainty on the offline selection is again set to 2.8%.

### $B^0 \rightarrow D_s^- K^+$ relative to $B^0 \rightarrow D^- \pi^+$

In this ratio, the PID uncertainty is a combination of the previous two ratios. The value is 1.5%.

The fit variations are processed similarly to above: the combinatorial is taken fully into account, and of the constraint means and background templates only the largest of the two values. The constrained fit range, fixed tail parameters and omitted  $\Lambda_b^0 \rightarrow D_s^{-(*)} p$  are all unique to one of the analyses, and are all taken into account. The resulting total systematic uncertainty is 3.5%.

The uncertainty on the offline selection is, once again, 2.8%.

Table 17: The systematic uncertainties on the ratios of branching fractions, obtained as described in the text. The totals are obtained by adding the other values in quadrature.

Systematic uncertainty	Value (%)		
	$\frac{B_s^0 \rightarrow D_s^- \pi^+}{B^0 \rightarrow D^- \pi^+}$	$\frac{B_s^0 \rightarrow D_s^\mp K^\pm}{B_s^0 \rightarrow D_s^- \pi^+}$	$\frac{B^0 \rightarrow D_s^- K^+}{B^0 \rightarrow D^- \pi^+}$
Particle identification	1.1	1.0	1.5
Fit model	2.8	1.2	3.5
BDT	2.8	2.8	2.8
Total	4.1	3.1	4.7

## 462 6.5 Consistency checks

463 In order to check the consistency of each fit as well as between the fits, a number of  
464 cross-checks is performed.

### 465 6.5.1 Misidentified background yields

466 For some background components resulting from a misidentified final state particle, the  
467 yield of that background can be compared to the expected yield, in parti. The expected  
468 yield is calculated by taking the number of signal decay events, multiplied with the  
469 misidentification probability, and corrected for the relative efficiencies (see Tables 4, 5,  
470 and 6), branching fractions, and hadronisation probabilities of the two processes. The  
471 branching fractions used for this fit are the current world average values [12], except for  
472 the branching fraction of the decay  $B_s^0 \rightarrow D_s^- \pi^+$ , which is obtained from Ref. [33]. The  
473 hadronisation fraction  $f_s/f_d = 0.259 \pm 0.015$  is also obtained from Ref. [33]. The yields of  
474 the misidentified background components, as listed in Table 18, are constrained in the  
475 nominal fit, and hence no discrepancy is expected by construction. Indeed, no tension is  
476 observed.

Table 18: Consistency checks comparing the expected yield of misidentified background components to the fitted yield. For convencience, the fitted misidentified yields include the errors from both the fit and the expected yield. The deviation is the difference between the expected and the fitted yield, in units of the corresponding error. Other processes are possible, but they are not observed due to the relative branching fractions.

	Expected yield	Fitted yield	Deviation
$B^0 \rightarrow D^- \pi^+$ fit			
$B^0 \rightarrow D^- K^+$	$4\,651 \pm 395$	$4\,257 \pm 468$	-0.73
$B_s^0 \rightarrow D_s^- \pi^+$	$7\,981 \pm 654$	$7\,463 \pm 750$	-0.60
$B_s^0 \rightarrow D_s^- \pi^+$ fit			
$B^0 \rightarrow D^- \pi^+$	$3\,339 \pm 271$	$3\,872 \pm 330$	1.39
$B_s^0 \rightarrow D_s^\mp K^\pm$ fit			
$B^0 \rightarrow D^- K^+$	$254 \pm 34$	$256 \pm 39$	0.05
$B_s^0 \rightarrow D_s^- \pi^+$	$2\,086 \pm 238$	$1\,979 \pm 252$	-0.35

### 477 6.5.2 Magnet polarity

478 The fit of the background components is done separately for two data samples: data  
479 corresponding to the LHCb magnet creating an upwards pointing magnetic field, and  
480 data corresponding to a downwards pointing magnetic field. The signal yields of the  
481 two samples, and the deviation from being equal to one another (after correcting for the  
482 difference in luminosity), are show in Table 19.

Table 19: Consistency checks comparing the expected relative yield of each magnet polarity. The luminosity values are the integrated luminosity in that particular sample, as a fraction of the total integrated luminosity used in the analysis. The yield values are results from the fit, and the errors are the statistical errors and systematic errors on the yield (arising from uncertainties in the fit model), added in quadrature. The deviation in  $\sigma$  is the number of standard deviations the expected yield differs from the observed yield. The deviation in % is the deviation as a fraction of the total yield (for both magnet polarities).

	Magnet up yield	Magnet down yield	Deviation ( $\sigma$ )	Deviation (%)
Luminosity	47.7%	52.3%		
$B^0 \rightarrow D^- \pi^+$	$217\,796 \pm 634$	$242\,643 \pm 679$	2.55	0.43
$B_s^0 \rightarrow D_s^- \pi^+$	$35\,827 \pm 233$	$39\,814 \pm 248$	0.97	0.37
$B^0 \rightarrow D_s^- K^+$	$1\,190 \pm 65$	$1\,182 \pm 68$	0.73	2.44
$B_s^0 \rightarrow D_s^\mp K^\pm$	$2\,384 \pm 69$	$2\,646 \pm 72$	0.20	0.33

## 7 Branching fractions

This section discusses the signal yields obtained from the fits and the resulting extraction of branching fractions. Section 7.1 contains the  $B_s^0 \rightarrow D_s^- \pi^+$  branching fraction, section 7.2 the branching fraction of  $B_s^0 \rightarrow D_s^\mp K^\pm$ , and section 7.3 discusses the relative and absolute branching fraction of  $B^0 \rightarrow D_s^- K^+$ .

### 7.1 Branching fraction of $B_s^0 \rightarrow D_s^- \pi^+$

The branching fraction of the decay  $B_s^0 \rightarrow D_s^- \pi^+$  is extracted using the following formula:

$$\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+) = \mathcal{B}(B^0 \rightarrow D^- \pi^+) \frac{\varepsilon_{B^0 \rightarrow D^- \pi^+} f_d N_{B_s^0 \rightarrow D_s^- \pi^+} \mathcal{B}(D^- \rightarrow K^+ \pi^- \pi^-)}{\varepsilon_{B_s^0 \rightarrow D_s^- \pi^+} f_s N_{B^0 \rightarrow D^- \pi^+} \mathcal{B}(D_s^- \rightarrow K^- K^+ \pi^-)}. \quad (2)$$

In this formula,  $f_d/f_s$  represents the ratio of hadronisation fractions of  $B^0$  mesons and  $B_s^0$  mesons;  $N_X$  is the measured yield of decay  $X$ , and  $\varepsilon_X$  the efficiency of process  $X$ . For  $f_s/f_d$ , the hadronic determination cannot be used, as that *relies* on the relative branching ratios that we determine. Instead, the independent semi-leptonic determination of  $f_s/f_d$  is used  $f_s/f_d = 0.268_{-0.0215}^{+0.0234}$  [16]. Updated values for the ratio of  $D$  and  $D_s$  branching fractions increases the value of  $f_s/f_d$  by 1.3%, whereas updated values of the ratio of lifetimes,  $(\tau_{B^0} + \tau_{B^-})/2\tau_{B_s} = 1.056 \pm 0.012$ , reduces it by 1.3%. The uncertainty due to the new inputs vary accordingly, resulting in  $f_s/f_d = 0.268_{-0.018}^{+0.020}$ . Finally, we use the semileptonic value, without any uncertainty on the  $D$  and  $D_s$  branching fractions, as they cancel in the determination of  $\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)$ ,

$$\frac{f_s}{f_d} = 0.268_{-0.016}^{+0.018}.$$

For the branching fractions appearing in the right-hand side of Eq.(2), the following values are used [12,33]:

$$\begin{aligned} \mathcal{B}(B^0 \rightarrow D^- \pi^+) &= (2.68 \pm 0.13) \times 10^{-3}, \\ \mathcal{B}(D^- \rightarrow K^+ \pi^- \pi^-) &= (9.13 \pm 0.19) \times 10^{-2}, \\ \mathcal{B}(D_s^- \rightarrow K^- K^+ \pi^-) &= (5.42 \pm 0.14) \times 10^{-2}. \end{aligned} \quad (3)$$

The relative yields and efficiencies can be found in Table 20. The systematic error on the branching fraction is a combination of the errors on the numbers in Eqs. (3) and the systematic uncertainties described in section 6. The yields used to extract the branching fraction are the combined yields for magnet up and down data.

Combining all the relevant numbers gives the following result:

$$\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+) = (2.98 \pm 0.02 \pm 0.16_{-0.20}^{+0.18}) \times 10^{-3},$$

where the errors are statistical, systematic, and due to  $f_s/f_d$ , respectively.

Table 20: Numbers entering the calculation of the branching fraction of the process  $B_s^0 \rightarrow D_s^- \pi^+$  relative to  $B^0 \rightarrow D^- \pi^+$ . The error on the ratio of yields is statistical, and that on the ratio of efficiencies is systematic, from the BDT and the PID.

$N_{B_s^0 \rightarrow D_s^- \pi^+} / N_{B^0 \rightarrow D^- \pi^+}$	$0.1643 \pm 0.0008$
$\varepsilon_{B^0 \rightarrow D^- \pi^+} / \varepsilon_{B_s^0 \rightarrow D_s^- \pi^+}$	$1.078 \pm 0.023$

## 508 7.2 Branching fraction of $B_s^0 \rightarrow D_s^\mp K^\pm$

509 The  $B_s^0 \rightarrow D_s^\mp K^\pm$  branching fraction is calculated in much the same way as that of  $B_s^0 \rightarrow D_s^- \pi^+$  in the previous section. The relevant numbers can be found in Table 21. The

Table 21: Numbers entering the calculation of the branching fraction of the process  $B_s^0 \rightarrow D_s^\mp K^\pm$  relative to  $B_s^0 \rightarrow D_s^- \pi^+$ . The errors are statistical and systematic, respectively.

$N_{B_s^0 \rightarrow D_s^\mp K^\pm} / N_{B_s^0 \rightarrow D_s^- \pi^+}$	$0.0665 \pm 0.0080$
$\varepsilon_{B_s^0 \rightarrow D_s^- \pi^+} / \varepsilon_{B_s^0 \rightarrow D_s^\mp K^\pm}$	$1.098 \pm 0.023$

510  
511 resulting ratio of branching fractions is

$$\frac{\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)}{\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)} = 0.0730 \pm 0.0015 \pm 0.0021,$$

512 where the first error is statistical and the second systematic. Combining this with the  
513 result for  $\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)$ , the following value is obtained:

$$\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm) = (2.22 \pm 0.05 \pm 0.13_{-0.15}^{+0.13}) \times 10^{-4},$$

514 where the errors are statistical, systematic, and resulting from  $f_s/f_d$ , respectively. The  
515 error from  $f_s/f_d$  enters through the branching fraction of  $B_s^0 \rightarrow D_s^- \pi^+$ .

## 516 7.3 Branching fraction of $B^0 \rightarrow D_s^- K^+$

517 Finally, the  $B^0 \rightarrow D_s^- K^+$  branching fraction, measured relative to that of  $B^0 \rightarrow D^- \pi^+$ , is  
518 determined using the numbers in Table 22. The resulting relative and absolute branching  
519 fractions are

$$\frac{\mathcal{B}(B^0 \rightarrow D_s^- K^+)}{\mathcal{B}(B^0 \rightarrow D^- \pi^+)} = 0.0117 \pm 0.0005 \pm 0.0007,$$

520 where the errors are statistical and systematic, respectively, and

$$\mathcal{B}(B^0 \rightarrow D_s^- K^+) = (3.14 \pm 0.12 \pm 0.14 \pm 0.18) \times 10^{-5}, \quad (4)$$

Table 22: Numbers entering the calculation of the branching fraction of the process  $B^0 \rightarrow D_s^- K^+$  relative to  $B^0 \rightarrow D^- \pi^+$ . The errors are statistical and systematic, respectively.

$N_{B^0 \rightarrow D_s^- K^+} / N_{B^0 \rightarrow D^- \pi^+}$	$(5.15 \pm 0.20) \times 10^{-3}$
$\varepsilon_{B^0 \rightarrow D^- \pi^+} / \varepsilon_{B^0 \rightarrow D_s^- K^+}$	$1.351 \pm 0.030$

521 where the first error is statistical, the second systematic, and the last one resulting from the  
522 branching fractions of  $B^0 \rightarrow D^- \pi^+$ ,  $D^- \rightarrow K^+ \pi^- \pi^-$ , and  $D_s^- \rightarrow K^+ K^- \pi^-$ , respectively.

## 8 Conclusion and discussion

The reported branching fraction measurements of  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B^0 \rightarrow D_s^- K^+$  are the current most precise values. The branching fraction of  $B_s^0 \rightarrow D_s^- \pi^+$  is compatible with the current world average value, which is dominated by the systematic uncertainty of the previous LHCb analysis.

### 8.1 Ratio of branching fractions $\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)/\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)$

The ratio of branching fractions of  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B_s^0 \rightarrow D_s^- \pi^+$  has a theoretical lower limit of [14]

$$\frac{\mathcal{B}(B_s^0 \rightarrow D_s^\mp K^\pm)}{\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)} \geq \frac{\varepsilon}{\mathcal{C}} [1 - y_s^2 \cos^2 \delta_s \cos^2(\phi_s + \gamma)] = 0.080 \pm 0.007. \quad (5)$$

In this formula,  $\varepsilon$  depends directly on CKM elements,  $y_s = \Delta\Gamma_s/2\Gamma_s$  is the relative decay width difference of the  $B_s^0$  meson system,  $\delta_s$  is the relative strong phase between the two ( $b \rightarrow c$  and  $b \rightarrow u$ ) tree topologies of the  $B_s^0 \rightarrow D_s^\mp K^\pm$  decay, and  $\phi_s + \gamma$  the relative weak phase. The factor  $\mathcal{C}$  depends on the differences in kinematics and decay topologies of the decays  $B_s^0 \rightarrow D_s^\mp K^\pm$  and  $B_s^0 \rightarrow D_s^- \pi^+$ :

$$\mathcal{C} = \frac{\Phi_{D_s\pi} \mathcal{N}_F \mathcal{N}_a \mathcal{N}_E}{\Phi_{D_s K}}.$$

Here, the  $\Phi$  are phase-space factors,  $\mathcal{N}_F$  contains the form factor and decay constant ratios,  $\mathcal{N}_a$  describes the ratio of the colour-allowed tree amplitudes of the decays, and  $\mathcal{N}_E$  contains corrections for the exchange topology, which only plays a role in  $B_s^0 \rightarrow D_s^\mp K^\pm$  (see Table 1).

In the previous analysis of this ratio by the LHCb collaboration [13], the reported value was  $0.0646 \pm 0.0043 \pm 0.0025$ , lower than both the theoretical lower bound and the measurement reported in this analysis. The value of the ratio of branching fractions presented here is compatible both with the previous measurement, and with the theoretical bound.

The theoretical lower bound could be reduced if one of the parameters has a different value than was assumed in the calculation. Most parameters in Eq. (5) are either relatively well known (such as the CKM elements) or do not affect the ratio much (such as the cosine term, which is suppressed by  $y_s^2 = 0.01$ ). Of all the parameters playing a role,  $\mathcal{N}_E$  is of particular interest, as it can be probed via decay processes that only occur through exchange topologies. By definition it equals

$$\mathcal{N}_E = \left| \frac{T}{T + E} \right|^2,$$

where  $T$  and  $E$  are directly related to the amplitudes of the corresponding tree and exchange diagrams, respectively.

553 Since branching fractions are related to the square of the amplitude,

$$\mathcal{B}(X \rightarrow Y) = \tau_X |A(X \rightarrow Y)|^2 \Phi_{X,Y}, \quad (6)$$

554 where  $\tau_X$  is the lifetime of particle  $X$  and  $\Phi_{X,Y}$  is a phase-space factor, a measurement  
 555 of the branching fraction does not contain information on the (complex) value of the  
 556 amplitude itself. Therefore, in order to get a handle on  $T$  and  $E$ , other decays are used,  
 557 which only occur through either tree or exchange diagrams [34]. The values of  $|T|$  and  
 558  $|E|$  can then be extracted using SU(3) symmetries between the three lightest quarks. In  
 559 particular, the following decay amplitudes are used:

$$\begin{aligned} \mathcal{B}(B^0 \rightarrow D^- K^+) &= (2.0 \pm 0.2) \times 10^{-4} \sim |A(B^0 \rightarrow D^- K^+)|^2 = |T|^2, \\ \mathcal{B}(B^0 \rightarrow D_s^- K^+) &= (3.1 \pm 0.3) \times 10^{-5} \sim |A(B^0 \rightarrow D_s^- K^+)|^2 = |E|^2, \\ \mathcal{B}(B^0 \rightarrow D^- \pi^+) &= (2.7 \pm 0.1) \times 10^{-3} \sim |A(B^0 \rightarrow D^- \pi^+)|^2 = |T + E|^2, \end{aligned} \quad (7)$$

560 of which the second is given in Eq. (4) and the other two are taken from Ref. [12].

561 To obtain information on the complex phases of these values, the values of  $|T|/|T + E|$   
 562  $|E|$  and  $|E|/|T + E|$  are compared. In the complex plane, these form, together with  
 563  $|T + E|/|T + E| = 1$ , a triangle, whose apex is determined by the imaginary parts of the  
 564 amplitudes. Recalculating these values using the numbers in Eq. (7) yields

$$\begin{aligned} \frac{|T|}{|T + E|} &= 0.99 \pm 0.11, \\ \frac{|E|}{|T + E|} &= 0.074 \pm 0.005. \end{aligned} \quad (8)$$

565 Because of the stability of the central values of the numbers in Eq.(8) compared to those  
 566 used to calculate the same quantity in Ref. [34], the resulting numbers are also stable.  
 567 In fact, since the central value of  $|T|/|T + E|$  remains the same, the lower bound on the  
 568 ratio of branching fractions is also unchanged. That value was calculated using precisely  
 569 measured numbers from decays into  $D^*$  mesons,  $\mathcal{N}_E^* = 0.966 \pm 0.056$ . An extra systematic  
 570 uncertainty of 5% was assigned for using the result for  $D$  mesons. Even when taking into  
 571 account the reduction in uncertainty obtained by the value of  $|T|/|T + E|$  in Eq. (8), the  
 572 uncertainty is not competitive with respect to  $\mathcal{N}_E^*$ :  $\mathcal{N}_E = 0.98 \pm 0.22$ . Therefore, the  
 573 lower bound is unchanged. The value for the ratio of branching fractions obtained in this  
 574 analysis is compatible with the lower bound within one standard deviation.

## 575 8.2 Further research

576 The logical next step is to repeat the analysis on  $B_s^0 \rightarrow D_s^\mp K^\pm$  in a time-dependent  
577 fashion. Doing so should reveal the  $B_s^0$ - $\bar{B}_s^0$  oscillations which lead to a measurement of  
578 the CKM angle  $\gamma$ . This is a complicated fit which has to take into account effects on the  
579 measured decay time distribution, amongst which detector acceptance and cross-feed of  
580 partially reconstructed, misidentified and combinatorial backgrounds. One way to reduce  
581 the combinatorial background is to further optimise and tighten the BDT cut, a process  
582 that was not applied in this analysis because the remaining combinatorial in fact allows  
583 its shape to be determined. Since the process  $B_s^0 \rightarrow D_s^\mp K^\pm$  only occurs through tree  
584 diagrams, very few New Physics models predict an enhancement of  $\gamma$ . On the other hand,  
585 this allows such a measurement that serves as a benchmark for other analyses with greater  
586 sensitivity to New Physics, like the charmless  $B_s^0$  decays to two hadrons which involve  
587 (penguin) loop diagrams.

588 Another interesting analysis that could be feasible with the currently available data is  
589 that of a separate analysis of  $D_s^- K^+$  and  $D_s^+ K^-$  final states. The relative contributions  
590 of CKM elements in these two processes enable a direct detection of  $CP$  violation in the  
591 yield difference between the two final states. The available statistics may limit the success  
592 of such an analysis.

593 **Appendices**

594 **A Fit templates**

595 This section contains the templates for the backgrounds used in the mass fits:  $B^0 \rightarrow D^- \pi^+$   
596 in section A.1,  $B_s^0 \rightarrow D_s^- \pi^+$  in A.2, and  $B_s^0 \rightarrow D_s^\mp K^\pm$  in A.3. The total yield of each  
597 background depends on the number of events in the sample of simulated data and is not  
598 actually used in the fit; each template is instead scaled to a predicted yield, as described  
599 in section 5.1.

## 603 B Signal shape fits

604 In order to determine the most accurate representation of the shape of the signal decay  
 605 processes, several shapes have been tried by fitting to a simulated sample of each of those  
 606 processes. In each of the following functions,  $N$  represents an overall, parameter-dependent  
 607 normalisation such that the integral of the function over  $\mathbb{R}$  is identically 1.

### 608 B.1 Cruijff function fit

609 Another probability distribution that has been tried is the so-called Cruijff function:

$$f(x; \bar{x}, \sigma_L, \sigma_R, \alpha_L, \alpha_R) = N \begin{cases} \exp\left(\frac{-(x - \bar{x})^2}{2\sigma_L + \alpha_L(x - \bar{x})^2}\right) & \text{for } x \leq \mu \\ \exp\left(\frac{-(x - \bar{x})^2}{2\sigma_R + \alpha_R(x - \bar{x})^2}\right) & \text{for } x > \mu. \end{cases} \quad (9)$$

610 The fits to this function can be found in Fig. 30, and the corresponding results for the  
 611 parameters in Table 23.

Table 23: Results of Cuijff function fits to simulated signal samples.

Parameter	Fitted value
<hr/> $B^0 \rightarrow D^- \pi^+$ <hr/>	
$\alpha_L$	$0.16172 \pm 0.00008$
$\alpha_R$	$0.10173 \pm 0.00003$
$\bar{x}$	$5284.6 \pm 78.8$
$\sigma_L$	$14.96367 \pm 0.00578$
$\sigma_R$	$14.70005 \pm 0.00932$
<hr/> $B_s^0 \rightarrow D_s^- \pi^+$ <hr/>	
$\alpha_L$	$0.15731 \pm 0.00134$
$\alpha_R$	$0.10532 \pm 0.00202$
$\bar{x}$	$5371.5 \pm 0.3$
$\sigma_L$	$14.45136 \pm 0.18365$
$\sigma_R$	$14.67946 \pm 0.18644$
<hr/> $B_s^0 \rightarrow D_s^\mp K^\pm$ <hr/>	
$\alpha_L$	$0.14220 \pm 0.00188$
$\alpha_R$	$0.09154 \pm 0.00335$
$\bar{x}$	$5371.2 \pm 0.3$
$\sigma_L$	$13.69576 \pm 0.23122$
$\sigma_R$	$14.62148 \pm 0.25504$

612 **B.2 Double Apollonios fit**

613 The final function shape that has been tried is the double-sided Apollonios function [35]:

$$f(x; \bar{x}, b, \delta, a, n_L, n_R) = N \begin{cases} \exp\left(-b\sqrt{1+a^2}\right) \left(\frac{(n_R\sqrt{1+a^2}-a)/(ba)-a}{(n_R\sqrt{1+a^2}-a)/(ba)-(x-\bar{x})/\delta}\right)^{n_R} & \text{for } \frac{x-\bar{x}}{\delta} > a \\ \exp\left(-b\sqrt{1+(x-\bar{x})^2/\delta^2}\right) & \text{for } \left|\frac{x-\bar{x}}{\delta}\right| \leq a \\ \exp\left(-b\sqrt{1+a^2}\right) \left(\frac{(n_L\sqrt{1+a^2}-a)/(ba)+a}{(n_L\sqrt{1+a^2}-a)/(ba)-(x-\bar{x})/\delta}\right)^{n_L} & \text{for } \frac{x-\bar{x}}{\delta} < -a \end{cases} \quad (10)$$

614 These fits are shown in Fig. 31 and the fitted parameter values in Table 24.

Table 24: Results of double Apollonios function fits to simulated signal samples.

b	$1.98925 \pm 0.01376$
$\delta$	$19.53861 \pm 0.05426$
$\bar{x}$	$5371.0 \pm 0.2$
$n_L$	$1.60698 \pm 0.04267$
$n_R$	$7.08174 \pm 0.37706$
$B_s^0 \rightarrow D_s^\mp K^\pm$	
a	$2.90476 \pm 0.01279$
b	$2.14334 \pm 0.02289$
$\delta$	$19.68621 \pm 0.08198$
$\bar{x}$	$5371.2 \pm 0.1$
$n_L$	$1.77328 \pm 0.09643$
$n_R$	$8.86130 \pm 1.33386$

Figure 31: Double Apollonios function signal fits for (a)  $B^0 \rightarrow D^- \pi^+$ , (b)  $B_s^0 \rightarrow D_s^- \pi^+$ , and (c)  $B_s^0 \rightarrow D_s^- K^+$ .

## 615 C Wrong-Sign fits

616 Fig. 32, 33, and 34 show the wrong-sign samples for the three different decay processes,  
 617 fitted with a function of the form

$$f(x; p_0, p_1) = p_0 + (1 - p_0) \exp(p_1 x).$$

618 The results of these fits are displayed in Table 11.

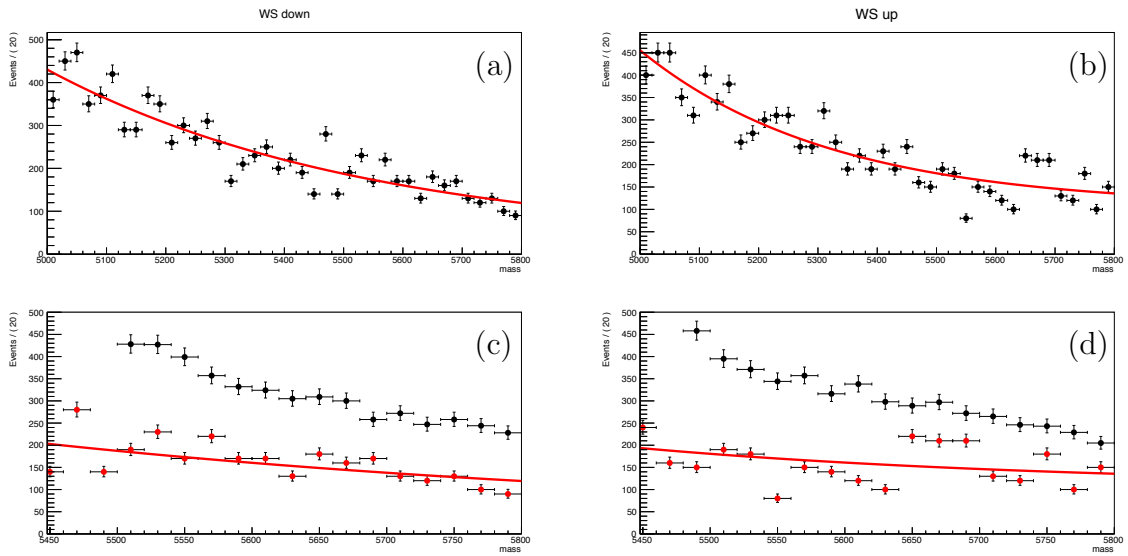

Figure 32:  $D^\pm\pi^\pm$  (wrong-sign) data and a fit to that data, for (a) magnet down and (b) magnet up. Also plotted are the same data and fit (in red) together with the normal (right-sign) data (in black), in close-up on the mass range [5450, 5800] MeV, for (c) magnet down and (d) magnet up.

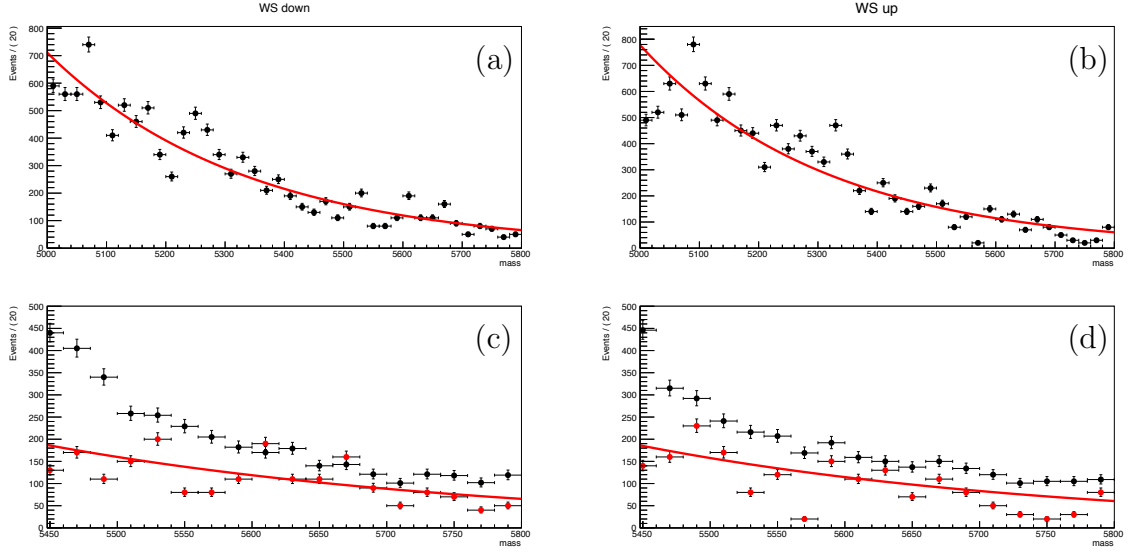

Figure 33:  $D_s^\pm \pi^\pm$  (wrong-sign) data and a fit to that data, for (a) magnet down and (b) magnet up. Also plotted are the same data and fit (in red) together with the normal (right-sign) data (in black), in close-up on the mass range [5450, 5800] MeV, for (c) magnet down and (d) magnet up.

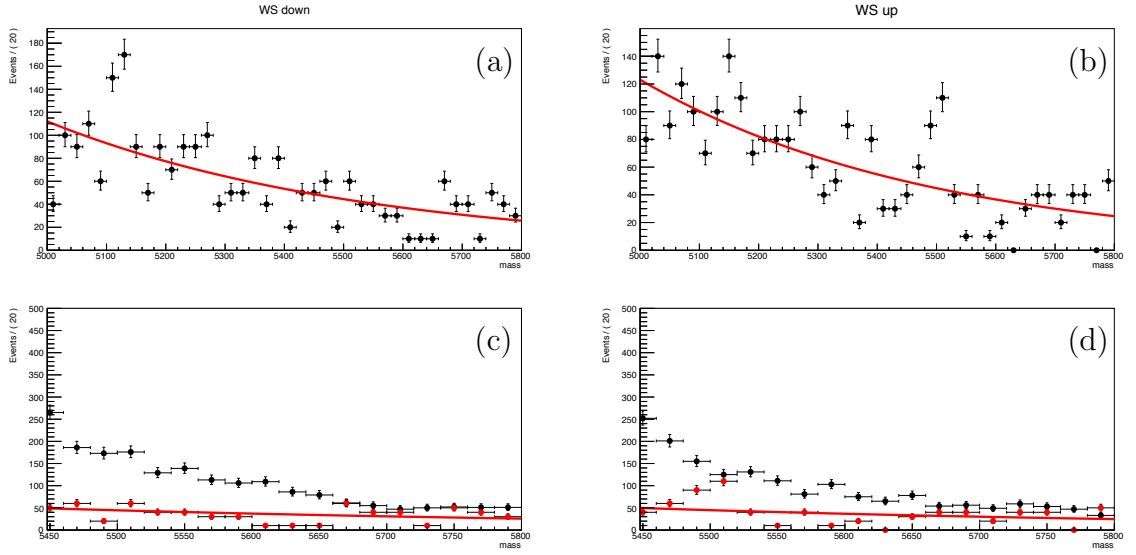

Figure 34:  $D_s^\pm K^\pm$  (wrong-sign) data and a fit to that data, for (a) magnet down and (b) magnet up. Also plotted are the same data and fit (in red) together with the normal (right-sign) data (in black), in close-up on the mass range [5450, 5800] MeV, for (c) magnet down and (d) magnet up.
